## Box Patent Application

Assistant Commissioner for Patents  
Washington, DC 20231

Presented for filing is a new original patent application of:

Applicant: **J. RICHARD AYLWARD**  
Title: **AUDIO SIGNAL PROCESSING**

Enclosed are the following papers, including those required to receive a filing date under 37 CFR §1.53(b):

	<u>Pages</u>
Specification	11
Claims	8
Abstract	1
Declaration	2
Drawing(s)	8

### Enclosures:

- Assignment cover sheet and an assignment, 2 pages, and a separate \$40.00 fee.
- Postcard.

Basic filing fee	760.00
Total claims in excess of 20 times \$18.00	504.00
Independent claims in excess of 3 times \$78.00	312.00
Fee for multiple dependent claims	0.00
Total filing fee:	<b>\$ 1576.00</b>

## AUDIO SIGNAL PROCESSING

The invention relates to processing audio signals, and more particularly to processing one or more audio input signals to provide more audio signals.

It is an important object of the invention to provide an audio signal processing system to provide a plurality of audio channel output signals from one or more input signals.

According to the invention, a method for processing a single channel audio signal to provide a plurality of audio channel signals includes separating the single channel audio signal into a first separated signal characterized by a frequency spectrum generally 10 characteristic of speech, and a second separated signal; generating a first channel signal from the first separated signal; and modifying the second separated signal to produce the remainder of the plurality of channel signals.

In another aspect of the invention, an audio signal processing apparatus for processing a single channel audio signal to provide a plurality of audio channel signals, 15 includes a speech separator for separating the audio signal into a first separated signal characterized by a frequency spectrum generally characteristic of speech, and a second separated signal; and a circuit coupled to the speech separator for generating a first subset of the plurality of audio channel signals from the second separated signal.,

In another aspect of the invention, an audio signal processing system includes an 20 input terminal for a single input channel signal; a center channel output terminal for a center channel output signal  $C$ ; a plurality of output terminals for a corresponding plurality of output channel signals; a speech separator inter-coupling the input terminal and the center channel output terminal for separating the single channel input signal into a speech audio signal and a nonspeech audio signal; and a circuit coupling the speech separator to the plurality of output terminals for providing, responsive to the nonspeech audio signal, a 25 corresponding plurality of audio channel signals on the output terminals.

In another aspect of the invention, a method for processing a single channel audio signal to provide two decodable audio channel signals decodable into five audio channel signals includes separating the single channel audio signal into a first separated signal characterized by a frequency spectrum generally characteristic of speech, and a second  
5 separated signal; processing the first separated signal to provide a center channel signal  $C$ ; modifying the second separated signal to provide a left channel signal  $L$ , a right channel signal  $R$ , a left surround channel signal  $L_S$ , and a right surround channel signal  $R_S$ ; combining the center channel signal, a sum of the left surround and the right surround channel signals and the left channel signal to produce a first of the two decodable audio  
10 channel signals; and combining the center channel signal, a sum of the left surround and the right surround channel signals and the right channel signal to produce a second of the two decodable audio channel signals.

In another aspect of the invention, a method for processing a single channel audio signal to provide three decodable audio channel signals subsequently decodable into five  
15 audio channel signals, comprises separating the single channel audio signal into a first separated signal characterized by a frequency spectrum generally characteristic of speech, and a second separated signal; processing the first separated signal to provide a center channel signal, the center channel signal comprising the first decodable audio signal; modifying the second separated signal to provide a left channel signal, a right channel  
20 signal, a left surround channel signal, and a right surround channel signal; combining a sum of the left surround and the right surround channel signals and the left channel signal to produce a second of the three decodable audio channel signals; and combining a sum of the left surround and the right surround channel signals and the right channel signal to produce a third of the three decodable audio channel signals.

25 In another aspect of the invention, a method for processing two input audio channel signals to provide more than two output audio channel signals includes separating each of the two input audio channel signals into a first separated signal characterized by a frequency spectrum generally characteristic of speech, and a second separated signal; combining the first separated signal of the first input audio channel signal and the first  
30 separated signal of the second input audio channel signal to form a first of the more than

two output audio channel signals; transmitting the second separated signal of the first input signal as a second of the more than two output audio channel signals; and transmitting the second separated signal of the second input signal as a third of the more than two output channel signals.

5        In still another aspect of the invention, an audio signal processing apparatus for processing two input audio channel signals to provide more than two output audio channel signals includes a first speech separator for separating a first of the two input audio channel signals into a first separated signal characterized by a frequency spectrum characteristic of speech to provide a first of the more than two output audio channel signals; a second speech separator for separating a second of the two audio channel signals into a first separated signal characterized by a frequency spectrum characteristic of speech, and a second of the more than two output audio channel signals; and a combiner for combining the first and second separated signals to form a third of the more than two output audio channel signals.

10      Other features, objects, and advantages will become apparent from the following detailed description, which refers to the following drawings in which:

15      FIG. 1 is a block diagram of a single channel audio signal processing system according to the invention;

20      FIGS. 2a and 2b are circuit diagrams of circuits implementing the speech separator and the multichannel emulator of FIG. 1;

25      FIGS. 3a -- 3c are block diagrams of alternate embodiments of the postemulation processing system of FIG. 1; and

FIG. 4 is a circuit diagram of a circuit implementing the principles of the invention in a two input channel system.

With reference now to the drawings and more particularly to FIG. 1, there is shown a single channel audio signal processing system according to the invention. Single channel signal input terminal 10 is connected to speech separator 12. Speech separator 12 is coupled to multichannel emulator 16 by nonspeech signal line 14 and is coupled to

postemulation processing system 20 by speech signal line 18. Multichannel emulator 16 is coupled to postemulation processing system 20 through emulated signal lines 22<sub>a</sub> – 22<sub>z</sub>. Speech separator 12 has two output taps, speech level tap 26 and nonspeech level tap 28.

In operation, a single channel signal, such as a monophonic audio signal is input at 5 input terminal 10. The single channel input signal is separated into a speech signal and a nonspeech signal by speech separator 12. The speech signal is output on line 18 as a first output channel signal to postemulation processing system 20. The nonspeech signal portion on line 14 is then processed by multichannel emulator 16 to produce multiple 10 output audio channel signals, which are then processed by postemulation processing system 20. The elements and function of postemulation processing system 20 will be shown in more detail in FIGS. 3a – 3d and explained in more detail in the corresponding portion of the disclosure.

Speech separator 12 may include a bandpass filter in which the pass band is a frequency range, such as 300 Hz to 3 kHz, or such as the so-called “A Weighted” filter 15 described in publication ANSI S1.4-1983, published by the American Institute for Physics for the Acoustical Society of America, which contains the range of frequencies or spectral components commonly associated with speech. Other filters having different characteristics may be used to account for different languages, intonations, and the like. Speech separator 12 may also include more complex filtering networks or some other sort 20 of speech recognition device, such as a microprocessor adapted for recognizing signal patterns representative of speech.

An audio signal processing system according to FIG. 1 is advantageous because transmissions or sources (such as videocassettes) having monophonic audio tracks can be presented on five channel audio systems with realistic “surround” effect, including 25 on-screen localization of dialog.

Referring now to FIG. 2a, there is shown one embodiment of a circuit implementing speech separator 12 and multichannel emulator 16. The circuit has a single input channel and five output channels. The input channel may be a monophonic audio

signal input, and the five output channels may be a left channel, a right channel, a left surround channel, a right surround channel and a center channel, as in a home theater system.

Speech separator 12 may include input terminal 10, which is coupled to the input 5 terminal of speech filter 80, to a + input terminal of first signal summer 82 and to a + input terminal of second signal summer 84. The output terminal of speech filter 80 is coupled to first multiplier 55 and to speech level tap 26 and is coupled to the – input terminal of first signal summer 82. The output of first multiplier 55 is coupled to center 10 channel signal line 22C and to the – input terminal of second signal summer 84. The output terminal of second signal summer 84 is coupled to multichannel emulator 16 through nonspeech content signal line 14. The output terminal of first signal summer 82 is coupled to nonspeech level tap 28.

Nonspeech content signal line 14 is coupled through delay unit 32 to a + input terminal of third signal summer 34, and a – terminal of fourth signal summer 36, thereby 15 providing multiple paths for processing the nonspeech signal. The output terminal of delay unit 32 is coupled to a – input terminal of fourth signal summer 36, to a + input terminal of seventh signal summer 46 and a + input terminal of eighth signal summer 48. The output terminal of third signal summer 34 is coupled to an input terminal of fifth 20 signal summer 38 and to an input terminal of second multiplier 40. The output terminal of fourth signal summer 36 is coupled to a + input terminal of sixth signal summer 42 and to an input terminal of third multiplier 44. The output terminal of fifth signal summer 38 is coupled to left channel signal line 22L and to a – input terminal of seventh signal summer 46. The output terminal of sixth signal summer 42 is coupled to right channel signal line 22R and to a + input terminal of eighth signal summer 48. The output terminal of seventh 25 signal summer 46 is coupled to right surround channel signal line 22Rs. The output terminal of eighth signal summer 48 is coupled to left surround signal line 22Ls. The output terminal of delay unit 32 is coupled to an input terminal of seventh signal summer 46 and to an input terminal of eighth signal summer 48.

Delay unit 32 may apply a 5ms delay to the signal. Third signal summer 34 may scale input from delay unit 32 by a factor of 0.5. Fourth signal summer 36 may scale input from delay unit 32 by a factor of 0.5. Seventh signal summer 46 and eighth signal summer 48 may scale their outputs by a factor of 0.5. First multiplier 55 may multiply the  
 5 input signal from speech filter 80 by a factor of  $\frac{|C|}{|C| + |\bar{C}|}$  (hereinafter  $\alpha$ ) where  $|C|$  is the time averaged magnitude of the speech signal on line 18 and  $|\bar{C}|$  is the time averaged magnitude of the complement of the speech signal.  $|C|$  and  $|\bar{C}|$  may be measured at speech tap 26 and nonspeech tap 28, respectively. Time averaging of  $|C|$  and  $|\bar{C}|$  may be done over a sample period, such as 300ms. Time averaging of the value of  $|C|$  may also be  
 10 done over two different time periods, such as 300mS and 30mS, combined, and scaled. Multipliers 40, 44, may multiply their inputs by a factor of  $\alpha$ .

For a monophonic input signal  $M$ , the circuit of FIG. 2a yields the following output signals at the following signal lines:

Signal Line	Channel	Signal	Value as $\alpha \rightarrow 0$	Value as $\alpha \rightarrow 1$
22C	Center	$\alpha C$	0	$C$
22L	Left (L)	$\bar{C} + .5\bar{C}\Delta t - \alpha(\bar{C} - .5\bar{C}\Delta t)$	$\bar{C} + .5\bar{C}\Delta t$	$\bar{C}\Delta t$
22R	Right (R)	$\bar{C} - .5\bar{C}\Delta t - \alpha(\bar{C} + .5\bar{C}\Delta t)$	$\bar{C} - .5\bar{C}\Delta t$	$-\bar{C}\Delta t$
22L <sub>s</sub>	Left Surround	$.5(\bar{C}\Delta t + R)$	$.5(\bar{C} + 1.5\bar{C}\Delta t)$	0
22R <sub>s</sub>	Right Surround	$.5(\bar{C}\Delta t - L)$	$.5(-\bar{C} + 1.5\bar{C}\Delta t)$	0

Table 1.

where  $C$  represents the speech content of signal  $M$ ,  $\bar{C}$  represents the nonspeech content of signal  $M$ ,  $\bar{C}\Delta t$  represents the nonspeech content of signal  $M$  delayed in time,  $L$  represents the left channel signal,  $R$  represents the right channel signal, and  $\alpha$  is as defined above.

5 Referring now to FIG. 2b, there is shown a second embodiment of a circuit implementing speech separator 12 and multichannel emulator 16. The circuit includes single input channel and five output channels. The input channel may be a monophonic audio input, and the five output channels may be a left channel, a right channel, a left surround channel, a right surround channel and a center channel, as in a home theater  
10 system.

The circuit of FIG. 2b is substantially identical to the circuit of FIG. 2a, except that in FIG. 2b, the input of multiplier 55 is directly coupled to input terminal 10 rather than to the output of speech filter 80, and the signal on center channel signal line 22C is scaled by a factor of 1.414.

15 A circuit according to the invention is advantageous because it can provide realistic five channel effect from monophonic signals. In the left and right channels, the  $\bar{C}$  components are in phase, but the  $.5\bar{C}\Delta t$  components are out of phase, which results in a stereo effect. In the left surround and right surround channels, the  $\bar{C}$  component are out of phase, which prevents localization on the left surround and right surround channels.  
20 The speech content of signal  $M$  is radiated by the center channel only, and is scaled to provide the appropriate power level so that speech is localized on the screen and is of the appropriate level.

A circuit according to the invention is also advantageous because total signal power is maintained. As can be seen in the circuit if FIGS. 2a and 2b, and table 1, the  
25 variable gain  $a$  is directly applied to the signal in channel 22C and the signal  $\alpha(\bar{C} + .5\bar{C}\Delta t)$  is subtractively combined with the signal in channels 22L and 22R so that increase in

variable gain  $a$  results in an increase in signal strength of the signal in channel 22C and a decrease in signal strength in the signals in channels 22L and 22R.

A circuit according to the invention is also advantageous of because the relative proportion of the sound radiated by speakers connected to the various channels is appropriate relative to the speech content of the monophonic input signal. If input signal  $M$  contains no speech, then  $C$  approaches zero,  $\bar{C}$  approaches  $M$ , and  $\alpha$  approaches zero. In this situation, there is no signal on the center channel and the signals on the other channels are as shown in Table 1. If signal  $M$  is predominantly speech, then  $C$  approaches  $M$ ,  $\bar{C}$  approaches zero, and  $\alpha$  approaches one. In this case, the signal in the left and right surround channels approaches zero, and the signal on the left and right channels approaches  $\bar{C}\Delta t$  and  $-\bar{C}\Delta t$ , respectively. Since the signal is delayed, the center channel is the source of first arrival information, and information from the complementary channels arrives later in time, so that a listener will localize on the radiation from the center channel. When the signal is predominantly speech, the signals on the left surround and right surround channels approach zero, so that there is no radiation from the surround speakers.

A further advantage of the circuit according to the invention is that the combining effect of the circuit is time-varying so that the perceived sources of the left and right channels are not spatially fixed.

Referring to FIGS. 3a – 3d, there are shown alternate embodiments of postemulation processing system 20. In FIG. 3a, signal lines 22L, 22L<sub>S</sub>, 22R, 22R<sub>S</sub> and 22C may be coupled to respective electroacoustical transducers 52L, 52L<sub>S</sub>, 52R, 52R<sub>S</sub>, and 52C which radiate sound waves corresponding to the signals on signal lines 22L, 22L<sub>S</sub>, 22R, 22R<sub>S</sub> and 22C, respectively. Electroacoustical transducers 52L, 52L<sub>S</sub>, 52R, 52R<sub>S</sub>, and 52C may be the left, left surround, right, right surround, and center channel speakers of a home theater system.

In the embodiment of FIG. 3b, postemulation processing system 20 may include a crossover network 54, which couples signal lines 22L, 22L<sub>S</sub>, 22R and 22R<sub>S</sub> to tweeters respective tweeters 56L, 56L<sub>S</sub>, 56R, and 56R<sub>S</sub> and to subwoofer 58 and signal line 22C

may be coupled to electroacoustical transducer 60. Tweeters 56L, 56LS, 56R, and 56RS may be the left, left surround, right, and right surround speakers, subwoofer 58 may be the subwoofer, and electroacoustical transducer 60 may be the center channel of a subwoofer/satellite type home theater system.

5 In the embodiment of FIG. 3c, postemulation processing system 20 may include a circuit for downmixing the outputs of multichannel emulator 16 into three channel signals suitable for recording, transmission or for playback on a three-channel system. Input terminals of ninth signal summer 62 are coupled to signal lines 22LS and 22RS. The output terminal of ninth signal summer 62 is coupled to an input terminal of tenth signal summer  
10 64 and an input terminal of eleventh signal summer 66. Signal from ninth signal summer 62 to tenth signal summer 64 may be scaled by a factor of 0.707, and signal from ninth signal summer 62 to eleventh signal summer 66 may be scaled by a factor of -0.707. An input terminal of tenth signal summer 64 may be coupled to signal line 22L so that the output signal of tenth signal summer 64 is  $0.707(L_S + R_S) + L$ , (where  $L_S$ ,  $R_S$ , and  $L$   
15 represent the inputs from signal lines 22LS, 22RS, and 22L respectively) which is output at left channel output terminal 86L. Input of eleventh signal summer 66 may be coupled to signal line 22R so that the output of eleventh signal summer 66 is  $-0.707(L_S + R_S) + R$ , (where  $L_S$ ,  $R_S$ , and  $R$  represent the inputs from signal lines 22LS, 22RS, and 22R respectively) which is output at right channel output terminal 86R. Signal line 22C is  
20 coupled to center channel output terminal 86C.

In the embodiment of FIG. 3d, postemulation processing system 20 includes a circuit for downmixing the output signals of multichannel emulator 16 into two channel signals suitable for recording, transmission, or for playback on a two-channel system. Input terminals of signal summer 62 are coupled to signal lines 22LS and 22RS. The  
25 output terminal of ninth signal summer 62 is coupled to an input terminal of tenth signal summer 64 and an input terminal of eleventh signal summer 66. Signal from ninth signal summer 62 to tenth signal summer 64 may be scaled by a factor of 0.707, and signal from ninth signal summer 62 to eleventh signal summer 66 may be scaled by a factor of -0.707. An input terminal of tenth signal summer 64 is coupled to signal line 22L so that the

output signal of tenth signal summer 64 is  $0.707(L_S + R_S) + L$ , (where  $L_S$ ,  $R_S$ , and  $L$  represent the signals on signal lines  $22L_S$ ,  $22R_S$ , and  $22L$  respectively). The output terminal of tenth signal summer 64 is coupled to an input terminal of twelfth signal summer 68. An input terminal of eleventh signal summer 66 may be coupled to signal line 5  $22R$  so that the output signal of eleventh signal summer 66 is  $-0.707(L_S + R_S) + R$ , (where  $L_S$ ,  $R_S$ , and  $R$  represent the inputs from signal lines  $22L_S$ ,  $22R_S$ , and  $22R$  respectively). The output terminal of eleventh signal summer 66 is coupled to an input terminal of thirteenth signal summer 70. Signal from first multiplier 55 to tenth signal summer 68 may be scaled by a factor of 0.707, so that output signal of tenth signal summer 68 is 10  $.707C + 707(L_S + R_S) + L$ , (where  $L_S$ ,  $R_S$ ,  $L$ , and  $C$  represent the inputs from signal lines  $22L_S$ ,  $22R_S$ , and  $22L$  and from first multiplier 55 respectively). The output terminal of tenth signal summer is coupled to left channel terminal output  $84L$ . Signal from first multiplier 55 to thirteenth signal summer 70 may be scaled by a factor of 0.707, so that output of thirteenth signal summer 70 is  $.707C - 707(L_S + R_S) + L$ , (where  $L_S$ ,  $R_S$ ,  $L$ , and  $C$  15 represent the inputs from signal lines  $22L_S$ ,  $22R_S$ ,  $22L$ , and  $22C$ , respectively). The output terminal of thirteenth signal summer 70 is coupled to right channel output terminal  $84R$ .

The embodiments of FIGS. 3c and 3d are advantageous because they can be rerecorded or retransmitted in two- or three-channel format and subsequently decoded for presentation in five-channel format.

20 Referring now to FIG. 4, there is shown a circuit implementing the principles of the invention in a two input channel system. Left input channel terminal  $90L$  is coupled to an input of left speech filter  $92L$  and additively coupled with left summer  $94L$ . The output of speech filter  $92L$  is differentially coupled with an input of left summer  $94L$  and additively coupled with center summer  $96C$ . The output of left summer  $94L$  is coupled 25 with left channel output terminal  $98L$  and left surround summer  $94L_S$  and differentially coupled with right surround summer  $94R_S$ . Right input channel terminal  $90R$  is coupled to an input of right speech filter  $92R$  and additively coupled with right summer  $94R$ . The output of speech filter  $92R$  is differentially coupled with an input of right summer  $94R$  and additively coupled with center summer  $96C$ . The output of right summer  $94R$  is coupled

with right channel output terminal 98R and right surround summer 94R<sub>S</sub> and differentially coupled with left surround summer 94L<sub>S</sub>. The output of left surround summer 94L<sub>S</sub> is coupled to left surround output terminal 98L<sub>S</sub> and output of right surround summer 94R<sub>S</sub> is coupled to right surround output terminal 98R<sub>S</sub>.

5        In operation a two-channel input signal, such as a stereophonic signal having left and right channels is input at input terminals 90L and 90R, respectively. The circuit separates the speech band portion of the signal, combines the left speech band portion  $C_L$  and the right speech band portion  $C_R$ , combines them, and scales them to form a center channel signal which is output at center channel terminal 98C. The nonspeech portion of  
10      the left channel signal and the nonspeech portion of the right channel signal are output at left channel output terminal 98L and right channel output terminal 98R, respectively. The output of center channel terminal 98C may then be used as the center channel of a three- or five-channel audio system. The output of left channel output terminal 98L and right channel output terminal 98R can then be used as the left and right channels of a three  
15      channel system. If a five channel output is desired, the output of summer 94R may be differentially combined with the output of summer 94L and scaled to form the left surround channel signal which is output at left surround output terminal 98L<sub>S</sub>, and the output of summer 94L may be differentially combined with the output of summer 94R and scaled to form the right surround channel signal which can be output at the right surround  
20      output terminal 98R<sub>S</sub>.

Other embodiments are within the claims.

What is claimed is:

1        1. A method for processing a single channel audio signal to provide a plurality of  
2        audio-channel signals, comprising:

3                separating said single channel audio signal into a first separated signal  
4        characterized by a spectral pattern generally characteristic of speech, and a second  
5        separated signal;

6                processing said first separated signal to provide a first audio-channel signal; and  
7                modifying said second separated signal to produce the remainder of said plurality  
8        of audio-channel signals.

1        2. A method for processing an audio signal in accordance with claim 1, wherein  
2        said modifying includes:

3                dividing said second separated signal into a plurality of signals; and  
4                multiplying one of the latter signals by a predetermined factor.

1        3. A method for processing an audio signal in accordance with claim 2, wherein  
2        said factor is variable with respect to time.

1        4. A method for processing an audio signal in accordance with claim 2 wherein  
2        said factor applies a gain that is proportional to the time averaged magnitude of said first  
3        separated signal divided by the sum of the time averaged magnitude of said first separated  
4        signal and the time averaged magnitude of said second separated signal.

1        5. A method for processing an audio signal in accordance with claim 1, wherein  
2        said modifying includes

3                dividing said second separated signal into a plurality of signals; and  
4                *at least one of* *and said plurality of signals*  
time-delaying said second separated signal.

1        6. A method for processing an audio signal in accordance with claim 1, wherein  
2        said modifying step provides a left channel signal and a right channel signal.

1        7. A method for processing an audio signal in accordance with claim 6, wherein  
2    said modifying step further provides a left surround channel signal and a right surround  
3    channel signal.

1        8. A method for processing a single channel audio signal in accordance with claim  
2    1, wherein said first audio channel signal is a center channel signal.

1        9. A method for processing a single channel audio signal in accordance with claim  
2    8, wherein said processing said first separated signal includes multiplying said first  
3    separated signal by a first predetermined factor.

1        10. A method for processing a single audio signal in accordance with claim 9,  
2    wherein said modifying step comprises the step of multiplying said second separated signal  
3    by a second predetermined factor.

1        11. A method for processing a single audio signal in accordance with claim 10,  
2    wherein said first predetermined factor and said second predetermined factor are  
3    determined such that an increase the signal strength of said first separated signal coincides  
4    with a decrease in the signal strength of said second separated signal.

1        12. A method of processing a single channel audio signal in accordance with claim  
2    9, wherein said first predetermined factor is variable with respect to time.

1        13. A method for processing a single channel audio signal in accordance with  
2    claim 9, wherein said predetermined factor is proportional to the time averaged magnitude  
3    of said first separated signal divided by the sum of the time averaged magnitude of the first  
4    separated signal and the time averaged magnitude of the second separated signal.

1        14. An audio signal processing apparatus for processing a single-channel audio  
2    signal to provide a plurality of audio channel signals, comprising  
3        a separator, for separating said audio signal into a first separated signal  
4    characterized by a frequency spectrum characteristic of speech, and a second separated  
5    signal; and  
6        a first circuit coupled to said separator responsive to said second separated signal

7 for providing a first subset of said plurality of audio channel signals, coupled to said  
8 speech separator.

1 15. An audio signal processing apparatus in accordance with claim 14, wherein  
2 said first circuit comprises multiple signal paths for said second separated signal,  
3 one of said multiple signal paths furnishing a time delay.

1 16. An audio signal processing apparatus in accordance with claim 14, wherein  
2 said first circuit comprises multiple signal paths,  
3 at least one of said multiple signal paths comprising a multiplier.

1 17. An audio signal processing apparatus in accordance with claim 16, wherein  
2 said first multiple signal paths are constructed and arranged to subtractively combine a  
3 signal to which said variable gain has been applied with a signal path to which said variable  
4 gain has not been applied.

1 18. An audio signal processing apparatus in accordance with claim 14, wherein  
2 said first subset of said plurality of audio channel signals comprises a left channel signal  
3 and a right channel signal.

1 19. An audio signal processing apparatus in accordance with claim 18, wherein  
2 said first subset of said plurality of audio channel signals comprises a left surround channel  
3 signal and a right surround channel signal.

1 20. An audio signal processing apparatus in accordance with claim 14, wherein  
2 said separator includes a bandpass filter having a pass band corresponding substantially to  
3 the band of spectra characteristic of speech.

1 21. An audio signal processing apparatus in accordance with claim 14, further  
2 comprising a second circuit coupled to said separator and responsive to said first  
3 separated signal for providing a second subset of said plurality of audio channel signals.

1 22. An audio signal processing apparatus in accordance with claim 21, wherein  
2 said second subset comprises a single audio channel signal.

1 23. An audio signal processing apparatus in accordance with claim 22, wherein  
2 said single audio channel signal is a center channel signal.

1        24. An audio signal processing system comprising;  
2              an input terminal for a single input channel signal;  
3              a center channel output terminal for a center channel output signal C;  
4              a plurality of other output terminals, for a corresponding plurality of other output  
5              audio channel signals;  
6              a separator for separating said single channel input signal into a speech audio  
7              signal and a nonspeech audio signal;  
8              a first circuit coupling said speech audio signal to said center channel terminal, and  
9              a second circuit, coupling said separator and said plurality of output terminals  
10          responsive to said nonspeech signal, providing a corresponding plurality of other audio  
11          channel signals.

1        25. An audio signal processing system in accordance with claim 24, wherein said  
2          second circuit comprises multiple signal paths,  
3              one of said multiple signal paths furnishing a time delay.

1        26. An audio signal processing system in accordance with claim 24, wherein said  
2          circuit comprises multiple signal paths,  
3              at least one of said multiple signal paths comprising a multiplier.

1        27. An audio signal processing system in accordance with claim 26, wherein said  
2          multiplier is coupled to an other output terminal that is a left channel output terminal

1        28. An audio signal processing system in accordance with claim 26, wherein said  
2          multiplier is coupled to an other output terminal that is a right channel output terminal.

1        29. An audio signal processing system in accordance with claim 24, wherein said  
2          separator comprises a bandpass filter having a pass band corresponding substantially to the  
3          spectrum of speech signals.

1        30. An audio signal processing system in accordance with claim 24, further  
2          comprising a multiplier coupling said separator to said center channel output terminal and  
3          multiplying the output of said separator by a predetermined factor.

1       31. An audio signal processing system in accordance with claim 30, wherein said  
2 predetermined factor is variable with respect to time.

1       32. An audio signal processing system in accordance with claim 30 wherein said  
2 predetermined factor is proportional to the time averaged magnitude of said speech audio  
3 signal.

1       33. An audio signal processing system in accordance with claim 32 wherein said  
2 predetermined factor is proportional to the time averaged magnitude of said speech audio  
3 signal divided by the sum of the time averaged magnitude of the speech audio signal and  
4 the time averaged magnitude of said nonspeech audio signal.

1       34. An audio signal processing system in accordance with claim 24, wherein said  
2 second circuit provides a left channel signal  $L$ , a right channel signal  $R$ , a left surround  
3 channel signal  $L_s$ , and a right surround channel signal  $R_s$ ,

4           further comprising a downmixing circuit coupled to said plurality of other output  
5 terminals and to said center channel output terminal, for downmixing said plurality of  
6 other output audio channel signals and said center channel signal to provide a plurality of  
7 decodable audio channel signals.

1       35. An audio signal processing apparatus in accordance with claim 34, wherein  
2 said plurality of decodable audio channel signals consists of two decodable audio channel  
3 signals.

1       36. An audio signal processing apparatus in accordance with claim 34, wherein  
2 said plurality of decodable audio channel signals consists of three decodable audio channel  
3 signals.

1       37. A method for processing a single channel audio signal to provide two  
2 decodable audio channel signals decodable into five audio channel signals, comprising:

3           separating said single channel audio signal into a first separated signal  
4 characterized by a spectral pattern generally characteristic of speech, and a second  
5 separated signal;

6           processing said first separated signal to provide a center channel signal  $C$ ;

7 processing said second separated signal to provide a left channel signal  $L$ , a right  
8 channel signal  $R$ , a left surround channel signal  $L_S$ , and a right surround channel signal  $R_S$ ;

9 combining said center channel signal, the sum signal of said left surround and said  
10 right surround channel signals, and said left channel signal to produce a first of said two  
11 decodable audio channel signals; and

12 combining said center channel signal, said sum of said left surround and said right  
13 surround channel signals, and said right channel signal to produce a second of said two  
14 decodable audio channel signals.

1 38. A method for processing a single channel audio signal in accordance with claim  
2 37, further comprising scaling said center channel signal and said sum of said left surround  
3 and said right surround channel signals by center and surround factors respectively

1 39. A method for processing a single channel audio signal in accordance with claim  
2 38, further comprising reversing the phase of said sum component comprising one of said  
3 first and second decodable audio signal relative to said sum component comprising the  
4 other decodable audio signal.

1 40. A method for processing a single channel audio signal to provide three  
2 decodable audio channel signals subsequently decodable into five audio channel signals,  
3 comprising:

4 separating said single channel audio signal into a first separated signal  
5 characterized by a spectral pattern generally characteristic of speech, and a second  
6 separated signal;

7 processing said first separated signal to form a center channel signal comprising a  
8 first decodable audio signal;

9 processing said second separated signal to provide a left channel signal, a right  
10 channel signal, a left surround channel signal, and a right surround channel signal;

11 combining a sum of said left surround and said right surround channel signals with  
12 said left channel signal to produce a first of said two decodable audio channel signals; and

13 combining said sum of said left surround with said right surround channel signals,  
14 and said right channel signal to produce a third of said decodable audio channel signals.

1        41. A method for processing a single channel audio signal in accordance with claim  
2        40, further comprising scaling by a predetermined surround factor.

1        42. A method for processing a single channel audio signal in accordance with claim  
2        41 further comprising reversing the phase of one of said sum comprising one of said  
3        second and third decodable audio signals relative to the other of and said second and third  
4        decodable audio signals.

1        43. A method for processing two input audio channel signals to provide more than  
2        two output audio channel signals comprising:

3                separating each of said two input audio channel signals into a first separated signal,  
4        characterized by a spectral pattern generally characteristic of speech, and a second  
5        separated signal;

6                combining said first separated signal of said first input audio channel signal with  
7        said first separated signal of said second input audio channel signal to form a first of said  
8        more than two output audio channel signals;

9                said second separated signal of said first input signal comprising a second of said  
10      more than two output audio channel signals; and

11                said second separated signal of said second input signal comprising a third of said  
12      more than two output channel signals.

13        44. A method for processing two input audio channel signals in accordance with  
14        claim 43, wherein said second separated signal of said first input signal comprises a  
*provides* 15        ~~provides~~ a left channel signal and said second separated signal of said second input signal  
*OK* 16        comprises a right channel signal.

1        45. A method for processing two input audio channel signals in accordance with  
2        claim 43, wherein said first of said more than two output audio channel signals comprises  
3        a center channel signal.

1        46. A method for processing two input audio channel signal in accordance with  
2        claim 43, further comprising  
3                differentially combining said second separated signal of said first input signal with  
4        said second separated signal of said second input signal to form a fourth of said more than

5 two output audio channel signals; and  
6 differentially combining said second separated signal of said second input signal  
7 with said second separated signal of said first input signal to form a fifth of said more than  
8 two output audio channel signals.

1 47 An audio signal processing apparatus for processing two audio channel signals  
2 to provide more than two output audio channel signals comprising,

3 a first separator, for separating a first of said two audio channel signals into a first  
4 separated signal characterized by a spectral pattern characteristic of speech and a second  
5 separated signal comprising a first of said more than two output audio channel signals;

6 a second separator, for separating a second of said two audio channel signals into a  
7 first separated signal characterized by a spectral pattern characteristic of speech, and a  
8 second separated signal comprising a second of said more than two output audio channel  
9 signals; and

10 a first combiner, for combining said first separated signal of said first audio channel  
11 signal and said first separated signal of said second audio channel signal to provide a third  
12 of said more than two output audio channel signals.

1 48. An audio signal processing apparatus in accordance with claim 47, further  
2 comprising

3 a second combiner for differentially combining said first output audio channel  
4 signal with said second output channel signal to provide a fourth of said more than two  
5 output audio channels; and

6 a third combiner for differentially combining said second output audio channel  
7 signal with said first output audio channel to provide a fifth of said more than two output  
8 audio channels.

Abstract of the Disclosure

10 Processing a single channel audio signal provides a plurality of audio channel signals by separating the single channel audio signal into a first separated signal, characterized by a spectral pattern generally characteristic of speech, and a second separated signal processed to provide the remainder of the plurality of audio output channel signals.

PATENT

ATTORNEY DOCKET NO. 02103/347001

IN THE UNITED STATES PATENT AND TRADEMARK OFFICE

Applicant : J. Richard Aylward  
Filed : Herewith  
Title : AUDIO SIGNAL PROCESSING

Art Unit:

Assistant Commissioner for Patents  
Washington, DC 20231

POWER OF ATTORNEY AND ELECTION OF  
ASSIGNEE TO CONDUCT PROSECUTION

The undersigned, the owner of the entire right, title and interest in the above-identified application filed herewith, elects to exclusively conduct the prosecution of this application in accordance with the provisions of 37 C.F.R. § 3.71 and appoints as attorney of the undersigned

Charles Hieken  
FISH & RICHARDSON P.C.  
225 Franklin Street  
Boston, Massachusetts 02110-2804  
Telephone: (617) 542-5070  
Facsimile: (617) 542-8906  
Reg. No. 18,411

to prosecute said application and to transact all business in the Patent and Trademark Office connected therewith with full powers of substitution. Please send all correspondence and direct all telephone calls to the above attorney at the above address, telephone number and facsimile number.
